

Advanced numerical methods for polymer materials under various strain rates

Dayou Ma, Andrea Manes

COMPORTAMENTO MECCANICO E MODELLAZIONE DEI POLIMERI AD ALTI STRAIN RATES

PRIMA GIORNATA DI STUDIO DEL GRUPPO DI LAVORO AIAS "XTREMA" (MATERIALS AT EXTREMES)

Contents

Objective:

- 1. Numerical methods for polymer materials subject to loading conditions under different strain rate
- 2. Considering the **presence of** defects for a **better understanding of the fracture behaviour** Outline:
- Background
- □ Cohesive-based model under tension (strain rate effect oriented)
- □ Stochastic FE model under compression (present of defect oriented)
- Conclusion

Background – existence of defects

Defects in polymer materials can hardly be avoided, their presence may be useful to **better understanding fracture behaviour** under **different strain rate** [1]

Molecular-scale defects, i.e., short chain, chain gathering...

Defects in polymers

Macroscale defects, i.e., voids, scratches...

Background – RTM6 epoxy resin

RTM6 is a **premixed epoxy-amine system**, composed by the tetra-functional epoxy resin and the harder. In the current activies, tensile and compressive samples were prepared as the validation of the numerical methods.

The matrix RTM6 was supplied by Hexcel Composites.

Cohesive-based model under tension – experiments

Tensile tests were carried out in MST-DyMaLab (Ghent, Belgium) with an extremely small sample ($\emptyset 2.5 \times 6$ mm) of **RTM-6** using SHTB (Split Hopkinson **Tension** Bar). Additionally, high-speed camera was employed to capture the fracture behaviours during loading.

Experimental data

- Nonlinearity seems to be reduced under dynamic conditions
- Modulus increased noticeably under dynamic conditions
- Failure strain decreased under dynamic conditions but increased as the strain rate increased

Cohesive-based model under tension – numerical method

- The nonlinear behaviour when $\Delta < \Delta_d$ is used to capture the **plasticity of RTM-6** under quasi-static condition.
- Different behaviour for **cohesive element that suppose to replicate materials with defect**, and the peak arrives sooner in type – based on the fact that the possible stress concentration always occurs near defects, leading to an immediate peak.

Note: Defected cohesive model does not describe the behaviour of defect itself, but of the material containing defects.

Herein, the parameters can be determined as:

$$\sigma_f = 200 MPa [1], \tau_f = 47 MPa [2],$$

$$\alpha_0 = 0.5, \Delta_0 = 0.1, \Delta_d = 0.2, \Delta_f = 1, \Delta_f^d = 0.3, G_{IC} = 113 J/m^2 [3]$$

Cohesive-based model under tension – results

- □ Summary:
- The trend here depicted fit with experimental data
- With the change of the proportion about the defected elements, the curves can be altered.
- As the presence of defect increase of, the yield strength and modulus increase but the failure strain reduces.

Does it look like dynamic test results?

Stochastic FE model under compression – experiments

Part of tests were carried out in MST-DyMaLab (Ghent, Belgium) under **quasi-static compression.** Coupled with others experimental findings [1, 2], the **fracture behaviours of RTM6 under compression is variegated**: two types of failure can be found.

Stochastic FE model under compression numerical method

Unlike tensile case, introducing triaxiality dependance is important for simulations of compressive loading conditions because the stress state is complex.

PRIMA GIORNATA DI STUDIO DEI GRUPPO DI LAVORO AIAS "X

Stochastic FE model under compression – numerical method

Considering the presence of defects:

- The more the defects, the lower the failure strain. (accelarated failure)
- □ Material properties in each element is constant.
- Different strain-triaxiality relationships (for failure) were asigned on different elements for replicating the distribution of defects.
- □ Monte-Carlo simulation was used for different distributions.

Conclusions

- The fitting of the experimental curves with numerical models, by means of the proportion of defected elements (simulated by cohesive element), show that more defects seems to be activated (in the tests) as the strain rate increases, which leads to more cracks before the collapse of samples under high strain rates.
- Presence of defects seems to be one of the reasons for the strain rate effect of polymer materials (RTM-6 epoxy).
- The existence of the defects can influence both strain rate effect and the failure process.
- The **defects might be one of the key reasons for the two different failure modes** as reported in the literatures.
